# NIKA Pipeline output products VersionB.0

#### The NIKA collaboration and IRAM

August 23, 2016

#### Abstract

This note describes the data products that the NIKA collaboration intends to provide to external observers for the first NIKA open time observations in February 2014. These products are the calibrated Time Ordered Information, the maps, calibration results (such as the measured beam) and log files. We also describe the NIKA data specifically produced for the IRAM IMBFITS files. [vA.1: clarify the clean TOI product, vB.0 concerns OP2 Data release V0]

## 1 Maps

We provide maps as FITS files for all the individual scans and a combination of scans per source. The latter is computed by excluding anomalous scans, for which we estimate the quality to be significantly poor and would reduce the quality of the final combined map. Individual scan files are named with respect to the observed source and the scan number as IRAM\_MAP\_source\_scan\_1mm.fits and IRAM\_MAP\_source\_scan\_2mm.fits (e.g. IRAM\_MAP\_DR210H\_20121120s0161\_2mm.fits). Combined maps are named as IRAM\_MAP\_source\_combined\_1mm.fits and IRAM\_MAP\_source\_combined\_2mm.fits (e.g. IRAM\_MAP\_DR210H\_combined\_2mm.fits). Three maps are provided in extension 0 of the FITS files and ordered in the following order: surface brightness map (opacity corrected), standard deviation map, and exposure time per pixel (hit map normalized by sampling frequency). The list of the detectors and the scans used to compute the maps are given in extension 1 of the FITS file for both individual scan maps and combined maps. More detailed information is given in tables 1 and 2. We highlight in the following the main issues concerning the map making:

- The standard coordinate system used is Ra.–Dec. (tangential projection: RA—TAN, DEC–TAN) but Azimuth–Elevation maps are done for planets.
- We use a nearest grid point projection with a pixel size of 4 arcsec (this can be adjusted by request).
- A predefined header for map projection can be used upon request if provided by the observers
- Pixels of the maps that have not been sampled are set to dNaN for the flux maps and zero for the time per pixel maps (see Tab. 1). Pixels with less than two measurements are set to dNaN for the standard deviation maps.
- Zero level is set in all detectors timelines outside the source before combining them.
- Timelines are weighted by the inverse variance of the noise, which is computed outside the source.
- In the case of point source data, electronic and atmospheric contributions to the data are decorrelated using the standard method described in [1]. Basically, a common-mode timeline is built by averaging all timelines and avoiding on-source detectors at any sample. The common-mode is first scaled to each detector and then subtracted from the timelines using a simple regression procedure.
- For extended source data two decorrelation methods can be used. The first of them minimizes the noise but removes large scale structures. It is based on the same common-mode method described above but no masking the source. The second one is based in an iterative procedure. First, a simplified map is constructed using the former method so that the location of the source can be inferred. Then this information is used to mask the source when computing the common-mode. This method preserves large scales (up to the size of the array) but is noisier. Both methods are described in [1].

### 2 Calibration results

The calibration procedure is described in [1]. The main outputs associated to this procedure are listed below.

Extension	Axis	Content	Units	Comment
0	0	Flux density	Jansky/beam	Opacity corrected
0	1	Standard deviation	Jansky/beam	Estimated form the TOI
0	2	Observing time per pixel	second	Same as hit map normalized by sampling frequency
1		Info structure	_	See Tab. 2

Table 1: Map FITS files extension 0

Structure row	Content	Units	Comment
1	Number of scan used	none	
2	List of the scan used	none	Only one for individual scan maps
3	List of the KIDs used	none	Labeled by the detector number (numdet)
4	List of opacities of the given channel	none	Computed from skydips
5	List of the integration times	second	
6	Scan type	none	e.g. azimuth, elevation, lissajous

Table 2: Map FITS files extension 1.

#### 2.1 Spectral bandpasses

The spectral bandpasses are given for both frequencies in NIKA\_bandpass.fits. The first extension contains the 1.25 mm channel and the second extension contains the 2.05 mm channel. For both wavelengths, we provide the sampled frequency in GHz, the corresponding NIKA bandpass transmission and error, and a typical atmospheric transmission model for 2 mm of precipitable water vapor above the telescope. Note that the NIKA bandpass transmission is measured using a Martin-Puplett Interferometer with a Rayleigh-Jeans spectrum. Hence, color corrections have to be computed using a Rayleigh-Jeans spectrum as reference.

#### 2.2 Unit conversion coefficients

Unit conversion coefficients are given for both wavelengths in the file NIKA\_unit\_conversion.fits. The first extension contains the 1.25 mm channel and the second extension contains the 2.05 mm channel. The following conversion factors are provided by integrating the corresponding spectra over the NIKA bandpasses:

- $\bullet~{\rm K_{\rm CMB}}$  to  ${\rm K_{\rm RJ}}$
- Compton parameter y to  $K_{CMB}$
- K<sub>RJ</sub> to Jy/beam
- Jy/beam to Jy/sr accounting for the main beam only

#### 2.3 Average beams

Maps of the strong point sources (e.g. planets), used by external observers for calibration/focus/pointing, will be used to measure the beam at 1.25 mm and 2.05 mm. This will be done for the total map (all detectors combined) and up to 60 arcsec. We will also compute the solid angle covered by the beam as a function of angular radius. These values are included in the FITS file named NIKA\_beam.fits. The explicit content of these files is given in Tab. 3.

Structure row	Content	Units	Comment
1	Angular radius	arcsec	
2	Normalized beam response profile	none	To be trusted up to 60 arcsec
3	Statistical error on the beam response	none	
4	Angular radius up to which the beam is integrated	arcsec	
5	Angular coverage of the beam	$arcsec^2$	To be trusted up to 60 arcsec
6	Statistical error on the angular coverage	$arcsec^2$	

Table 3: Beam FITS files content. Values in extension 0 and 1 are for the 1.25 mm and 2.05 mm channels, respectively.

#### 2.4 Focal plane: projection of the array in the sky

Main focal plane properties are given in the file NIKA\_focal\_plane.fits. Values in extension 0 and 1 are for the 1.25 mm and 2.05 mm channels, respectively. The file includes:

- Position of the KIDs with respect to the telescope pencil beam in Nasmyth coordinates along the X axis.
- Position of the KIDs with respect to the telescope pencil beam in Nasmyth coordinates along the Y
- An estimate of the beam FWHM fitted for all detectors with an elliptical gaussian beam.
- An estimate of the beam FWHM along the X axis, fitted for all detectors with an elliptical gaussian beam.
- An estimate of the beam FWHM along the Y axis, fitted for all detectors with an elliptical gaussian beam.

### 3 NIKA data for IMBFITS

A subset of the raw NIKA data is included in the NIKA IRAM IBMFITS files that contain also pointing and extra observation information. These NIKA data in extension Params, include detector information in the form of parameters and flags for each detector. Important parameters are described here: in the header,  $AF\_MOD$  or  $BF\_MOD$  give the frequency (Hz) of the modulation. Table data contain: NUMDET, the KID official name, Array (= 1 or 2, for 1 and 2mm channels),  $ACQ\_BOX$  (0 or 1, the electronic readout box index), FREQUENCY the frequency (decaHz) of the tone, WIDTH the width of the resonance (decaHz), TYPE is (= 0 for non-existent KID (that should not happen as data are not transmitted, =1 for useable KIDs, =2 for OFF-resonance tones,  $\geq$  3 KIDs with problems) and finally  $K\_FLAG$  will contain another diagnosis (Flags per scan are similar to the definition given in the next section, Table 5).

We also provide Raw Time Ordered Information (rTOI) including common data (sample number and MJD) and detector data. In terms of detector data, in extension IMBF-backendNIKAxmm (with x=1 or 2, per subscan), we include for each detector and for each sample the raw in phase (I) and in quadrature (Q) values of the transmission of the detector and their derivatives (dI) and (Q), the transformed quantities (Q) and (Q) are an estimate of the change of the resonance frequency of the detector (the basic quantity needed to be projected on the sky), (Q) and (Q) are that is an estimate of the resonance total frequency of the detector, which is linear with the total power but of lower accuracy, so it is used only for opacity corrections. Only data for valid detectors are included.

Here is a summary description of the parameters of instrument that can be found in the KidParams extension header:

#### 4 Clean Time Ordered Information

The Clean Time Ordered Information (cTOI) is provided for both wavelengths (1 mm and 2 mm) in FITS files named iram30m-NIKAxmm-scan-clean\_imb.fits where scan is scan defines the observed scan using year + month + day + s + scan number and x is 1 or 2 (e.g. iram30m-NIKA2mm-20140223s8-clean\_imb.fits). These clean TOI FITS files include both detector (extension CleanNIKAdata) and common data (extension KidParams) as given in Tab. 4. They are written at the same place as for the raw fits files. Only valid detectors are retained (the number of valid detectors is written as NDET in the CleanNIKAdata extension header). This is done within the NIKA analysis pipeline after point-source calibration and without any decorrelation nor filtering. Note that glitches are flagged and interpolated in order not to bias spectral properties of the timelines. Along with the calibrated brightness (Jy/beam) for each detector, we give a flag which means that only data with a flag equal to zero should be projected on maps. The calibration of brightness involves the absolute calibration on Uranus, the opacity correction and the elevation-dependent beam efficiency correction. We then give the absolute RA-DEC instantaneous pointings of each detector (in degrees). For planets, the system is Az-El centered on 0,0 (see the XXYYTYPE keyword). We also give a robust common mode to help with a quick look (by simply projecting brightness minus common mode). That common mode is computed as the average of the detectors far enough of a given detector (20 arcseconds) which are the most correlated with it (we take at least 10 of them). It is computed on a per subscan basis. The OTF, pointing, Lissajous scans can be used. The other types (skydip, track, focus) should not be used (to be improved). In the IMBF-scan extension, we have added the NIKA measured zenith opacities at 1 and 2mm (NIKATAU1, NIKATAU2) as well as the median elevation (degree) of the scan. We have also insured the continuity of the samples across subscans in order to preserve power spectrum analyses. In the extension IMBF-antenna-s we have modified the DATE-OBS and DATE-END keywords to match the proper MJD of the start and end of each subscan. Not all scans could be processed for various reasons, the main one being the issue with recovering the pointing information during the February 2014 campaign.

We also provide overall flags that are computed by summing the powers of two of all the type of flags as  $\operatorname{Flag}_{\operatorname{Total}} = \sum_i \operatorname{Flag}_i \times 2^i$ , with  $\operatorname{Flag}_i$  set to one if flagged and zero otherwise. In this way, the overall flag value,  $\operatorname{Flag}_{\operatorname{Total}}$ , can be expressed in a binary basis such that digits correspond to individual flags values Valid data samples have therefore an overall flag value of zero. The meaning of the flag index i is given in Tab. 5. For example, a data sample for a KID that is out of resonance and for which a glitch has been flagged will have an overall flag value of  $\operatorname{Flag}_{\operatorname{Total}} = 2^0 + 2^3 = 9$ . This is equivalent to 0001001 in a binary basis, in which we identify the digit to the corresponding flag according to Tab. 5.

## 5 Instrument performance

A summary of basic instrumental performance will be provided in the form of an ascii table.

## 6 Log file

For every scan, we produce a log file logfile\_scan.txt (e.g. logfile\_20121120s0162.txt) that contains the list of parameters given in Table 6. This file will also give the list of parameters used in the processing described above (see talbe 7).

Structure row	Content	Units	Array type
1	Point-source calibrated detectors timelines	Jy/beam	$N_{\mathrm{KIDs}} \times N_{\mathrm{sample}}$
2	Flag timelines (see text and Tab. 5)	none	$N_{\mathrm{KIDs}} \times N_{\mathrm{sample}}$
3	R.A. detectors coordinates timelines in the sky	degree	$N_{\rm KIDs} \times N_{\rm sample}$
4	Dec. detectors coordinates timelines in the sky	degree	$N_{\mathrm{KIDs}} \times N_{\mathrm{sample}}$
5	Sample index	none	$N_{\rm sample}$
6	Time	second	$N_{\rm sample}$
7	MJD	Day	$N_{ m sample}$
8	LST	?	$N_{\rm sample}$
9	Elevation	radian	$N_{ m sample}$
10	Paralactic angle	radian	$N_{\rm sample}$
11	Scan azimuth offset	arcsec	$N_{\rm sample}$
12	Scan elevation offset	arcsec	$N_{ m sample}$
13	Subscan index	none	$N_{ m sample}$

Table 4: Time Ordered Information FITS files content.  $N_{\rm KIDs}$  represents the total number of valid detectors and  $N_{\rm sample}$  the number of samples in the file.

## 7 Data delivery

The IMBFITS files and the clean calibrated TOI are archived by IRAM and can be provided on request. Calibration products will be available on the NIKA wiki page: http://www.iram.es/IRAMES/mainWiki/NIKA/Main

The maps, associated figures and logfiles, are delivered to each project account under : /vis/xxx-13/observationData/nika

where xxx-13 is your project number. During the run, the products of a preliminary offline reduction will be provided as version v0. Then a version v1 will be delivered within a month. Observers may contact their respective NIKA instrument friend of project for information regarding the offline processing (http://www.iram.es/IRAMES/mainWiki/Continuum/PoolOrganization/1stNIKApool). Depending on feedbacks, a version v2 may be needed.

Flag label $i$	Flag power	Flag type	Dependency
0	1	Glitch in the reconstructed flux	KID and sample
1	2	Off resonance tone	KID
2	4	Saturated KID	KID and sample
3	8	Out of resonance KID	KID
4	16	Resonance overlap	KID
5	32	Cross talking detector	KID
6	64	Anomalous detector to be discarded	KID
7	128	RFdIdQ is not well computed	Sample
8	256	Not a proper part of the scan	Sample (e.g approach slew in Lissajous
9	512	Interpolated missing pointing data	Sample
10	1024	KIDs tuning	Sample
11	2048	Anomalous scan speed (e.g. between subscans, slews)	Sample
12	4096	Frequency scanning	Sample
13	8192	Frequency scanning blanking	Sample
14	16384	FPGA frequency change	Sample
15	32768	Tuning error	Sample
16	65536	Wrong resonance	Sample
17	131072	Lost resonance	Sample
18	262144	Scan status	Sample
19	524288	Dilution Temperature Glitch	Sample
20	1048576	Jump in the TOI	Sample
21	2097152	Common glitch to all kids of an array	Sample

Table 5: Description of the meaning of flags. See [2] for more details on the KIDs transfer function. The flag value of  $2^i$  corresponds to the flag type given in the table (see text for more details). Valid (to be projected on the map) data will have a total flag value of zero.

Variable	Unit	Comment
Scan number	none	e.g. 20121120s0161
Object	none	
$ au_{ m 1.25mm}$	none	Measure with NIKA using skydips
$ au_{2.05 ext{mm}}$	none	Measure with NIKA using skydips
Integration time	second	On-source time
Scan type	none	e.g. azimuth, elevation, lissajous
Mean elevation	radian	
Mean paratactic angle	radian	
Mean LST	I don't know	
Mean MJD	I don't know	
R.A. pointing coordinates	degree – arcmin – arcsec	
Dec. pointing coordinates	degree – hour – second	
IRAM 30-m latitude	degree	
IRAM 30-m longitude	degree	
IRAM 30-m altitude	meters
